## **Introduction**

Global Positioning System (GPS) measurements on the island of Hawaii began in 1987 and have proven to be a very effective tool in monitoring ground deformation associated with volcanic and volcano-tectonic activity (e.g. Dvorak, 1994; Owen et al., 1995). Sources of deformation on Hawaii include the magma chambers beneath the summits of Kilauea and Mauna Loa, the magma systems in their rift zones, and slip along detachment faults beneath the southern flanks of both volcanoes. From 1993 through 1996, Kilauea Volcano erupted almost continuously on the east rift zone from various vents in the Pu'u 'O'o area (Figure 1), continuing the eruption that began in January of 1983. There were, however, numerous pauses in eruptive activity. Most of these lasted only one to two days, but several longer pauses occurred in 1993 and 1996. The 1993 pause followed an upper east rift zone earthquake swarm on February 7 and continued until lava erupted from a new vent on the side of Pu'u 'O'o cone on February 20 (Heliker et al., in press). A summit intrusion on February 1, 1996, preceded a surge in supply to the eruption site, followed by a 10-day pause in eruptive activity. Another substantial pause started on May 30 and lasted until June 4, 1996 (Thornber et al., 1996).

Mauna Loa volcano, which last erupted in 1984, remained quiescent. Only one earthquake of magnitude greater than 5 was recorded on the island during this reporting period. This was a M5.2 earthquake on February 1, 1994, that originated at about 32 km beneath the south flank of Kilauea.

## **GPS at the Hawaiian Volcano Observatory (HVO)**

### **Equipment**

HVO acquired six Trimble SSE receivers in 1993, and Stanford University has nine Trimble SSE and SSI receivers. Both HVO and Stanford instruments are used in a once-yearly extensive survey on Kilauea Volcano. In the summer of 1993, two UNAVCO Ashtec MXII's were also employed. In 1996, Stanford purchased additional Trimble SSI receivers for the continuous GPS network. Table 1 lists receiver and antenna types for each of the instruments.

### **Survey Strategy**

Three surveying methods were implemented from 1993 through 1996: static, campaign-style surveys; rapid-static surveys; and continuously operating sites. The bulk of the data documented here was collected with static surveying methods, in which the GPS instrument is set up over a benchmark and records data every 30 seconds for 8 to 24 hours. At remote, secure locations, such as those accessible only by helicopter, GPS instruments are usually left on-site to record data over several days. In 1995, we established several rapid-static networks. In rapid-static surveying, receivers are set up at one or two sites to run for the duration of the survey, while other receivers occupy sites within about 15 km of the stationary receivers and collect data every 15 seconds for about 20 minutes at each site. This method allows just a few instruments and personnel to survey a relatively dense, small network in one day. In a collaborative effort in 1996, HVO and Stanford University began installing continuously recording GPS instruments on Kilauea Volcano. At these sites, GPS antennas are mounted on threaded stainless steel rods set into bedrock (except station UWEV, which is set into the top of a cement vault) and surrounded by an 8-inch diameter PVC pipe filled with

cement. These sites collect data every 30 seconds into 24-hour data files, which are transmitted daily to the observatory via radio modem. We collected data from satellites orbiting higher than 10 degrees above the horizon until October 1996, when we decreased the cut-off elevation angle to 5 degrees.

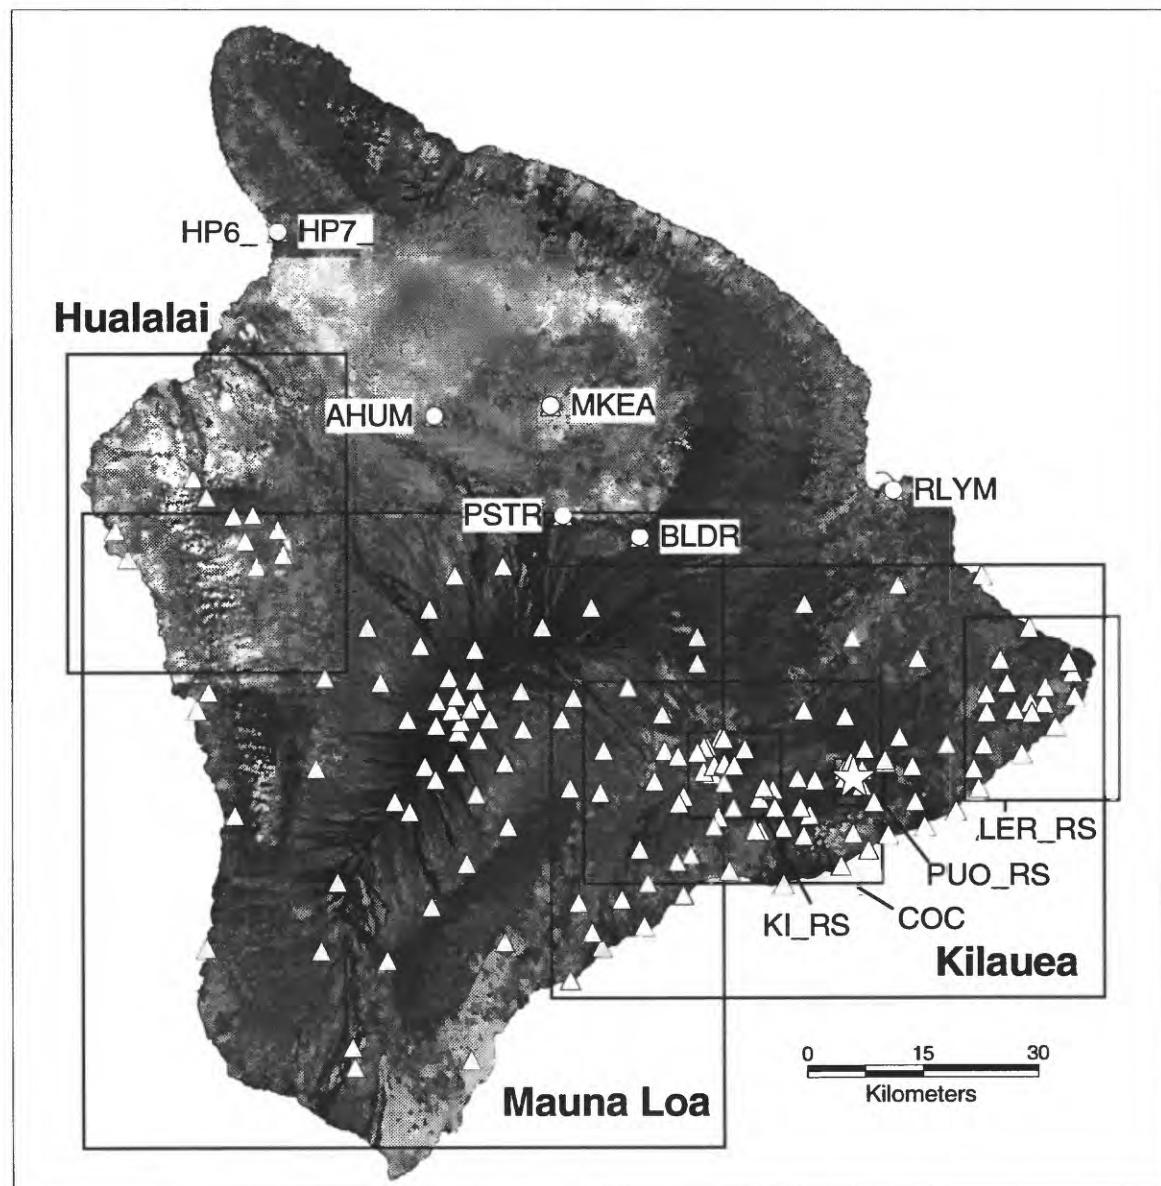

Figure 1. GPS benchmarks on the island of Hawaii. Boxes indicate areas of the network maps of Figure 2. Stations marked by a circle and labeled with 4-letter codes are often occupied with several networks, as they are located away from actively deforming areas and are used as local references for displacement calculations. The location of Pu'u 'O'o is indicated by the star.

## GPS Surveys

All the benchmarks and continuously operating receiver sites occupied with GPS between 1993 and 1996 are listed in Table 2, and locations are shown in Figure 1. Figure 2 subdivides the island into networks of benchmarks that are usually occupied during a single campaign. Note that some sites are common to more than one network. The Kilauea (ki) and Mauna Loa (ml) networks are usually occupied once yearly. The Hualalai (hl) network was established in 1995, and we plan to occupy it, as well as the west Mauna Loa (wml) network, about once every two years. The "Chain-of Craters" (coc) network was occupied, on average, every few months beginning in late 1993. Complete listings of the benchmarks occupied during each campaign are found in Table 3, and a similar listing, sorted by benchmarks, is in Table 4. Table 5 lists every GPS session from 1993 through 1996. Dates and occupation times are in UTC. Sessions often cross a UTC date boundary, and we assign the date for which the bulk of the data is collected to the filename. Antenna heights are slant heights to the bottom of the ground plane, unless otherwise noted, except for continuous sites, where the height listed in Table 5 represents a "rinex" height (vertical height to the bottom of the pre-amp base). Also listed are the formats in which the data are archived. Raw data were converted to rinex format with UNAVCO's trrinex software.

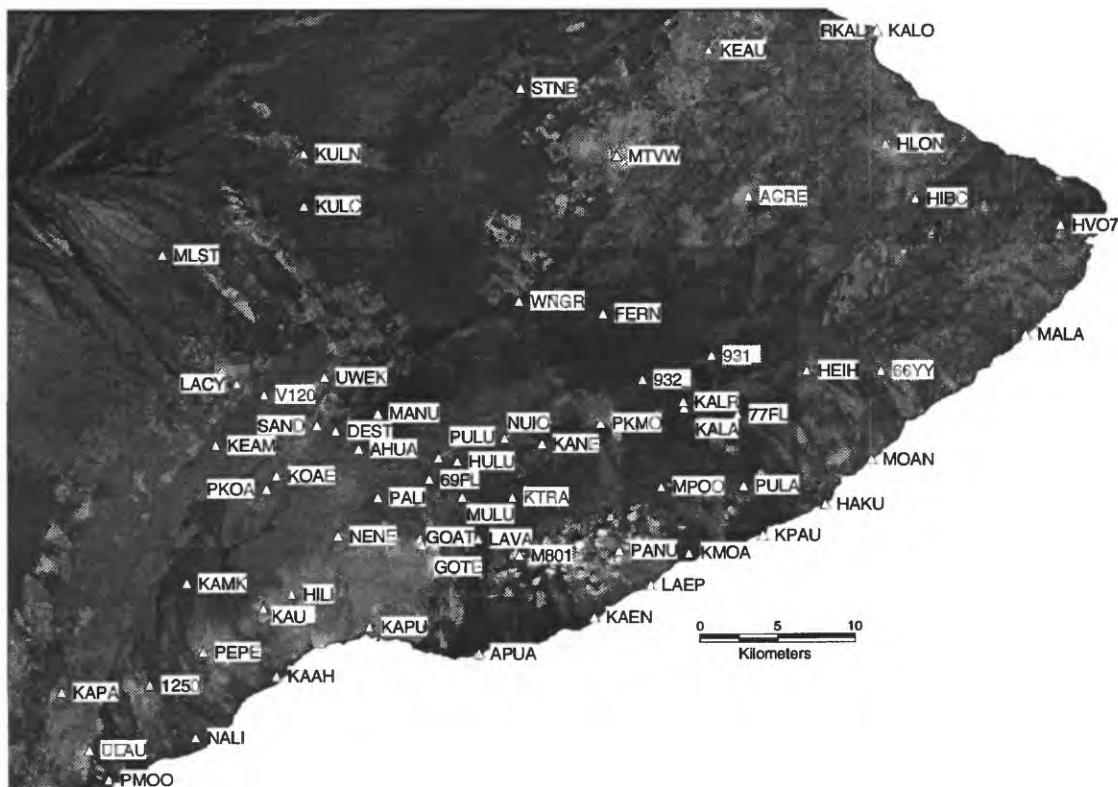

Figure 2a. The Kilauea GPS network.

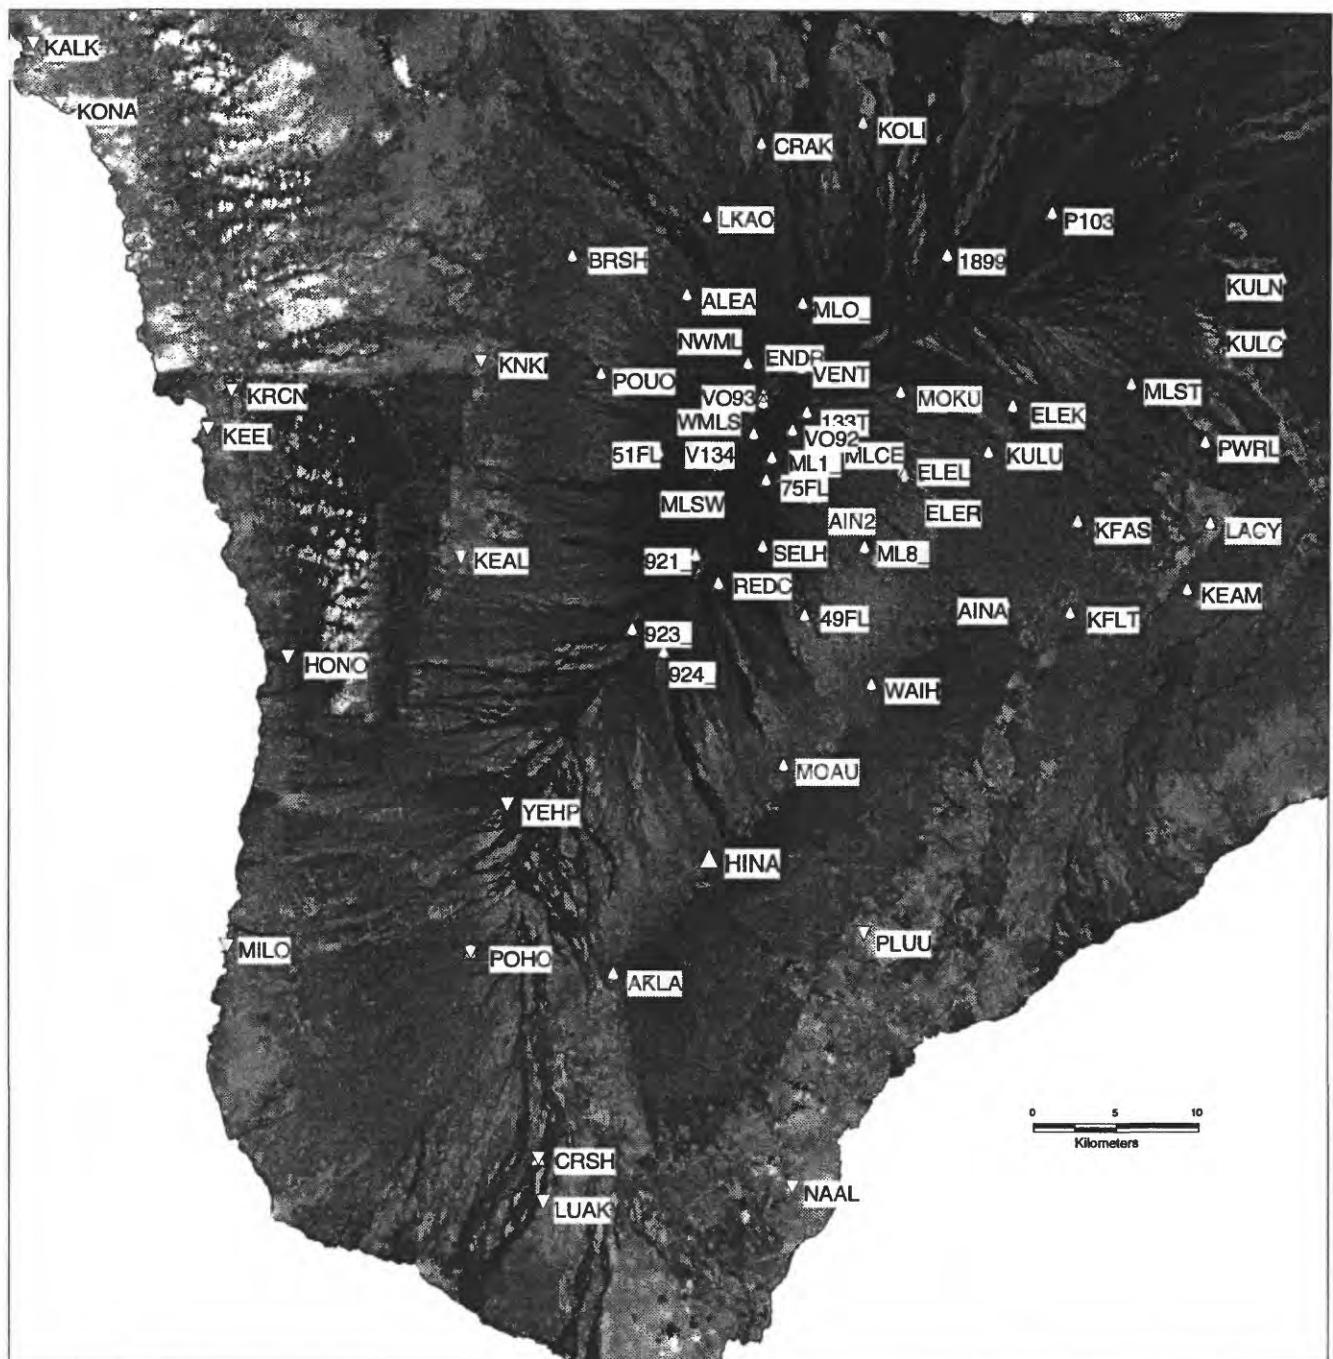

Figure 2b. The Mauna Loa GPS network. Stations on the west flank of Mauna Loa are usually occupied in separate campaigns ("wml" in tables) and are shown with inverted triangles.

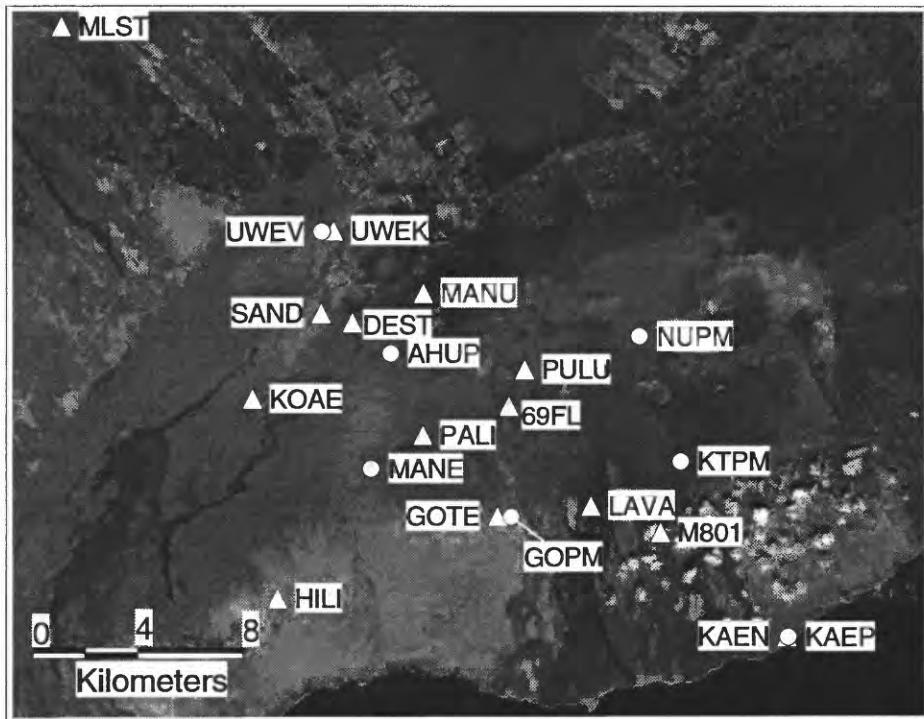

Figure 2c. The Chain-of-Craters and continuously operating GPS networks. Continuous sites are shown with circles.

## Data Processing

All data, with the exception of the rapid-static campaign data, were processed with NASA Jet Propulsion Lab's (JPL) GIPSY software using satellite orbital parameters determined by JPL. We used satellite orbits in the ITRF93 reference frame until July 1, 1996 and in ITRF94 afterward. Until August 1995, our processing strategy utilized the International GPS Service continuously operating receiver at Kokee Park, Kauai, as a reference clock. After August 1, 1995, we used satellite clock parameters provided by JPL. We determined station positions independently, without constraining the position of any particular site. Phase-cycle ambiguities were fixed to the best-fitting integer. We required elevation angles of satellites to be above 15 degrees until December 1995 and above 10 degrees thereafter. We find that the -5 degree change in cut-off angle caused an systematic change in calculated ellipsoid heights of about -1 cm. Kilauea campaign and continuous data were processed jointly by HVO and Stanford. Rapid-static data were processed with Trimble's GPSurvey software, which currently does not allow the option of using improved orbital parameters and does not provide a full covariance matrix for the solution. We are still evaluating the processing options for optimum results from rapid-static surveying.

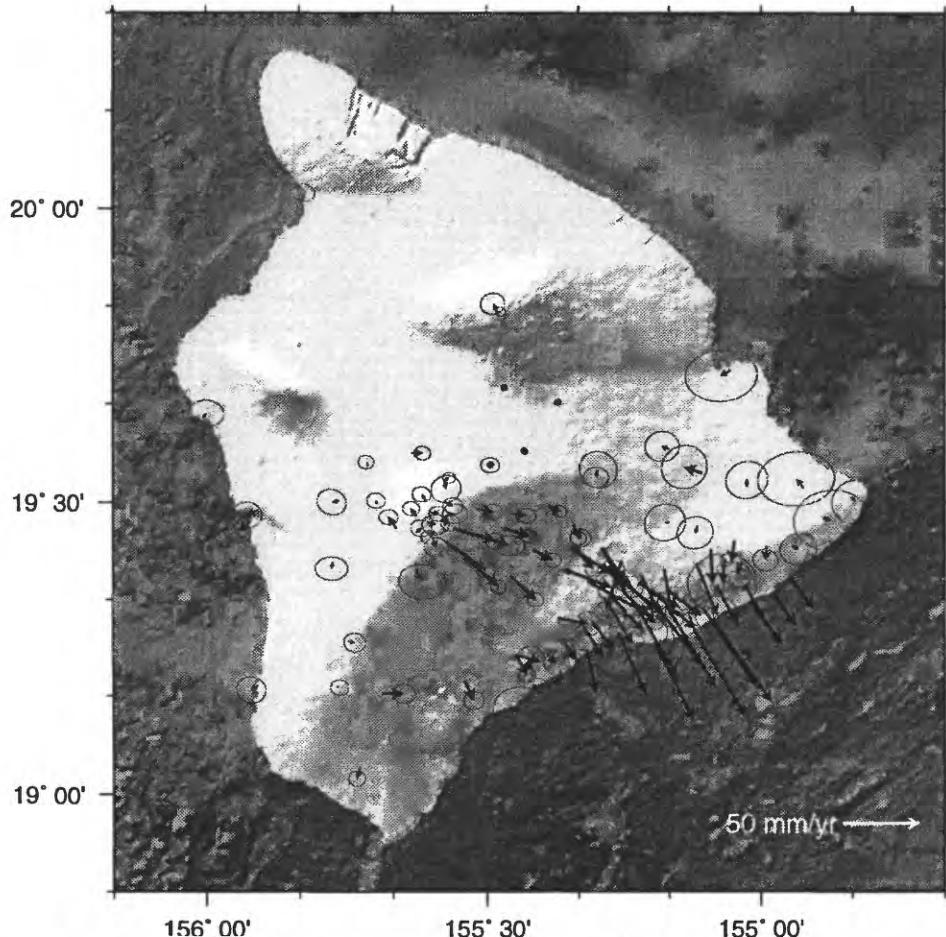

Figure 3. Average displacement rates from 1993 through 1996. Ellipses represent five times the standard error computed by GIPSY. All campaign-style data collected over this time period were used to constrain velocities.

## Results

The largest motions on the island from 1993 through 1996 were observed on the south flank of Kilauea (Figure 3), with maximum displacement rates of about 10 cm/yr, similar to rates observed with GPS from 1990 to 1993 (Owen et al., 1995a). However, not all stations moved at a constant rate over this time period. For example, displacement rates on Kilauea's south coast slowed to about 6 cm/yr between 1993 and 1994 (Owen et al., 1995b), and velocities on the southeastern flank of Mauna Loa varied from a maximum of over 4 cm/yr between 1993-94 to less than 2 cm/yr between 1995-96. The summit of Kilauea underwent substantial subsidence and contraction from 1993 to 1996, while Mauna Loa's summit, which had been extending and rising since its last eruption (Miklius et al., 1995), showed very low rates of deformation.

Figure 4 shows a time series of the data from the two longest-running continuous stations as an example of the data collected by the continuous GPS network. The network has shown great potential for monitoring both the long-term deformation and the variations in deformation rates that are crucial to understanding the relationship between the magma system and structure of Hawaii's active volcanoes.

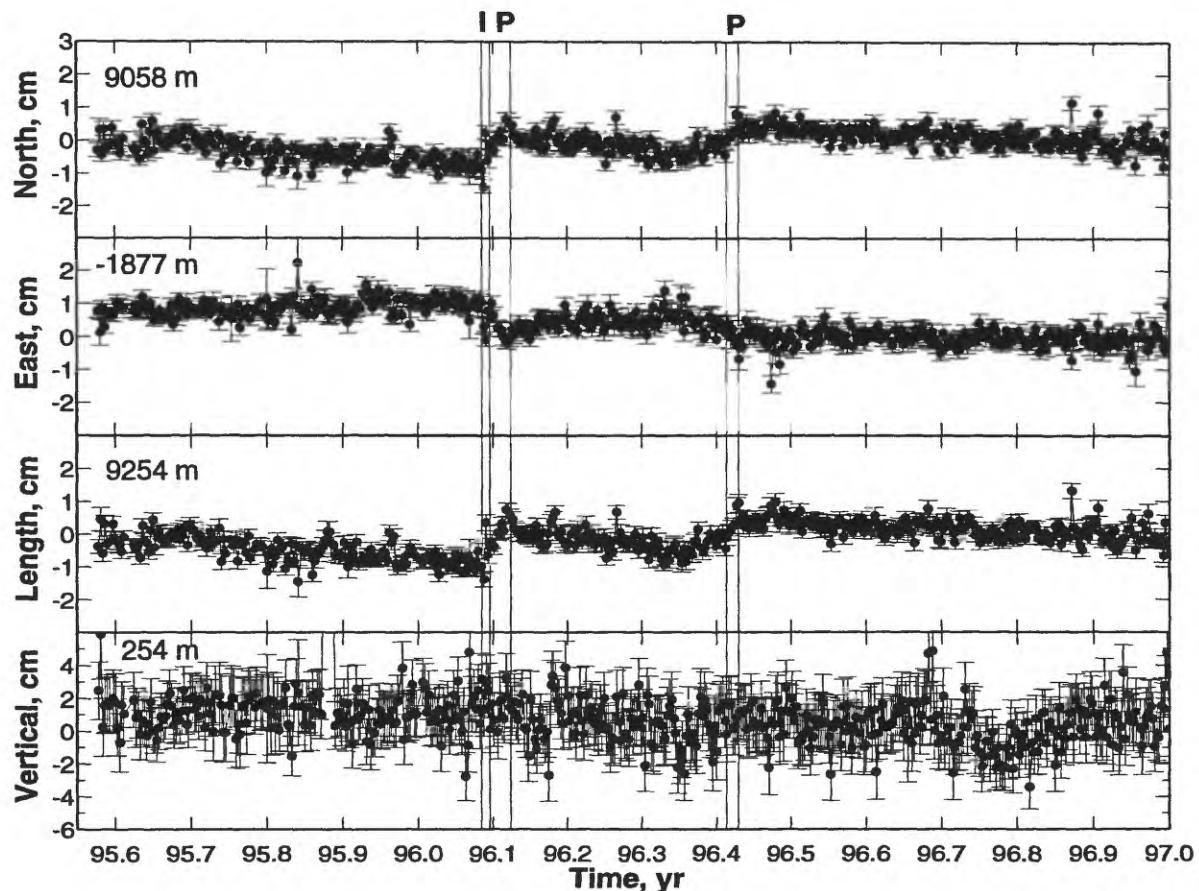

Figure 4. Time series of the motion of UWEV relative to MANE (see Figure 2 for locations). We have plotted the value of the component minus the mean value of that component over this time period. Approximate mean values are listed in the top left corner of each plot. Vertical lines mark the times of the 1996 intrusion and pauses discussed in the introduction.

## Acknowledgements

The number of people who assisted in gathering GPS data from 1993 through 1996 is too large to permit acknowledging each individual. Almost all of the staff and volunteers of the Volcano Observatory and numerous Stanford students have been involved in the GPS campaigns and we thank them all for their help. We would especially like to thank Jeff Freymueller, currently of the University of Alaska at Fairbanks, for his assistance in the installation and use of Gipsy software both at HVO and at Stanford.
